Appendix A. Prompt sheet....18

1. Executive summary

PetCare is a proposed mobile app that helps dog and cat owners understand common health concerns, receive cautious preliminary guidance with an urgency level, learn about animal care, and find a suitable veterinarian. It is designed for two groups: current pet owners, and people planning to adopt or buy a pet.

The project began with a client meeting in which a veterinary medicine company (represented by the course faculty) described a need for a separate digital product that could support its wider business. The app is intentionally kept separate from the client's medicine sales. Integration with the client's product catalogue is treated as a possible future extension, and the app does not recommend medicines or issue prescriptions.

This report documents the product thinking behind the wireframe: the problem, users, research plan, feature priorities, user journeys, nine wireframe screens built in Figma, a proposed REST API specification, and a plan to test and iterate the design. The client's indicative budget of ₹2,00,000 shapes a realistic MVP that defers complex AI diagnosis, video consultations and advanced integrations.

> **Scope of this deliverable**
>
> A low-fidelity, non-interactive wireframe and its documentation. No backend, working app, clinically validated AI model or live vet network has been built.

2. Client brief and decisions

2.1 What the client asked for

From the first client meeting, the requirements discussed were:

- A site or app, separate from the client's medicine business, that helps animal owners.
- A way to indicate possible symptoms in a pet and see what they may mean (a "scan" or symptom check).
- Recommendations for the problem, through a diet or care plan, or by connecting the owner to a recommended doctor.
- An information library where a person can search an animal and learn its diet, basic information, suitable environment, common health problems and what it needs to stay healthy.
- Proper endpoints (API routes) for each function, for example a defined endpoint for doctors.
- A budget of ₹2,00,000. Only a wireframe is required at this stage.

2.2 Decisions taken for version 1

Area	Decision	Status
Target users	Pet owners, and people planning to adopt or buy a pet	Proposed, [confirm with client]
Animals	Dogs and cats only. No livestock in version 1	Proposed, [confirm with client]
Platform	Mobile-first app	Proposed
Symptom check	Guided: symptom selection, duration, severity, follow-up questions, optional photo. Photos are supporting context only. No claim of photo diagnosis	Proposed, [confirm]
Vet directory	Searchable directory with profiles, specialties, locations, availability and appointment requests. Sample data only; no real integration	Proposed
Medicine business	App kept separate. Possible future catalogue integration. No medicine sales or automated prescriptions in version 1	Unconfirmed, [client to decide]
Design style	White background, dark green accents, light green cards, rounded corners, readable type, simple navigation	Proposed

3. Problem statement and objectives

> **Problem statement (draft, to be refined after research)**
> Pet owners often find it hard to interpret early signs of illness, to understand what a specific animal needs to stay healthy, and to decide when and where to seek veterinary care. They need a clear, trustworthy starting point and a straightforward route to qualified help.

3.1 Product vision

One easy-to-use place where owners keep their pets' details, describe a concern in a structured way, receive cautious guidance with a clear urgency level, learn how to care for an animal, and reach a veterinarian.

3.2 Objectives

- Make reliable care information easy to find and understand.
- Help owners describe symptoms clearly, using guided questions rather than free text.
- Communicate urgency cautiously and direct users to a veterinarian when appropriate.
- Help users find vets by location, specialty, animal type and availability.
- Help prospective owners judge whether an animal suits their home and lifestyle.
- Fit a realistic MVP inside the client's indicative budget.

3.3 Proposed success measures

Targets should be agreed with the client. Suggested measures for a future working version:

Measure	Why it matters
Symptom check completion rate	Shows whether the flow is short and clear enough
Share of results where users take a next step (find vet or read guide)	Shows whether guidance leads to action
Time to request an appointment	Shows how quickly users reach care
"Was this helpful?" rating	Early signal on trust and usefulness
Library searches that lead to a detail page	Shows value for prospective owners

4. Target users and personas

> **Important**
> The personas below are assumption-based starting points drawn from the client brief. They must be checked and updated using your real interview and survey findings before submission.

	Riya, 26	Amit, 42	Neha, 22
Who	First-time dog owner, working professional	Owns two cats, busy family household	Student thinking about adopting a pet
Goals	Know quickly if a symptom is serious; feel confident about care	Keep records and reminders in one place; find a trusted vet nearby	Learn what a pet needs before deciding; understand time and cost
Frustrations	Searches online and gets conflicting or alarming answers	Vet details and records are scattered	No single trustworthy source for comparing animals
Main screens	Symptom Checker, Result, Vet Directory	My Pets, Reminders, Vet Profile, Booking	Animal Library, Animal Details
Evidence	[quote or finding from your research]	[quote or finding]	[quote or finding]

4.1 Stakeholders beyond end users

Group	Interest
Veterinarians and clinics	Receive appointment requests with useful context. A vet-facing view is a possible future scope item
Client company	Platform supports the wider business and shows accurate, controlled information
Content reviewers (qualified vets)	Validate care guides and triage rules before launch

5. User research plan and competitor analysis

This section sets out how research will be done. Findings are placeholders to be completed with real data. Nothing here should be presented as an actual finding until you have collected it.

5.1 Research questions

1. How do pet owners currently decide whether a symptom needs a vet?
2. Where do they look for care information, and how much do they trust it?
3. What makes them hesitate to book a vet, or to trust a health app?
4. What do people considering a pet want to know before deciding?
5. Which features matter most: symptom guidance, vet booking, care guides, or reminders?

5.2 Methods

Method	Plan	Sample / sources	Status
Survey	About 8 questions (Appendix B), shared online	8–10 pet owners or prospective owners	[done / pending]
Short interviews	10–15 minutes each, using the guide in Appendix B	2–3 owners, and 1 vet or pet-store contact if possible	[done / pending]
Public forum review	Read and tag threads to learn how owners describe problems. Paraphrase; do not quote usernames. Use for language and frequency only, never as medical facts	30–50 threads across 3–4 public forums (for example Reddit pet communities, Quora, Indian pet groups)	[done / pending]
Authoritative content check	Validate care and triage content against veterinary references and, ideally, a practising vet	Merck Veterinary Manual, AVMA, WSAVA, ASPCA toxic list, Indian veterinary bodies	[done / pending]
Competitor analysis	Review 3–4 existing apps (table 5.3)	App stores and websites	[done / pending]

5.3 Competitor analysis

Method: desk research on public sources (company pages, app store listings, news coverage and software review sites), carried out on 26 October 2026. Five products were reviewed because each covers part of PetCare's scope: Indian vet-consult and commerce platform (Supertails), clinic-run booking and records app (PetDesk), AI photo screening (TTcare), guided symptom triage (TriageTail and Daisy), and an Indian pet-care management app (Vets and Care). Features change often, so [confirm each by installing or opening the app and add your own screenshots].

App (market)	Symptom guidance	Vet access and booking	Animal info and records	Strengths	Gap compared with PetCare
Supertails (India; dogs and cats focus)	No guided urgency triage evident on the pages reviewed. Help starts with a consult	Online consult booked by time slot; a vet calls within about 10 minutes of the slot. Post-consult kit with records, treatment plan and prescription. Own clinics (Supertails+, first opened in Bengaluru in 2025)	Online training content; pharmacy and product store. No species care library seen on pages reviewed	Strong brand, integrated online and offline care, pharmacy with discount on medicines after consult	Commerce-led: revenue includes product sales and pharmacy. Some customer reviews on its site mention long waits and missed confirmations. No free self-serve triage
PetDesk (US; clinic-branded)	None; focuses on clinic communication	24/7 appointment requests to the user's own clinic; reminders; messaging	Vaccination records, lab results, prescriptions, to-do lists, tips from the clinic	Large user base (company claims over 7 million owners); strong reminders and records	Works only when a clinic subscribes; US focus; no symptom guidance or animal library
TTcare (Korea; dogs and cats)	AI analysis of photos of eyes, skin and joints; company claims accuracy of about 90% or more	Virtual consults with vets and local vet visits	Health log, expert tips, video care guides	Differentiated image-based screening; CES 2023 Innovation Award honoree	Photo-based diagnosis claims carry safety and trust risk; subscription pricing (reported at $4.99 per month or $49.99 per year in 2023); not built around Indian vets
TriageTail and Daisy (US-led AI triage apps)	TriageTail listing: symptom-first intake for dogs and cats, follow-up chat, urgency labels Monitor, Urgent, Emergency. Daisy: chatbot gives care tips or advises a vet visit	Not evident in the listings reviewed	Case history; Daisy sends routine care reminders	Closest match to PetCare's checker; clear urgency framing	No vet directory or booking evident in the excerpts reviewed; no animal library; not India-specific
Vets and Care (India)	Not evident	Remote consultations with vets	Health tracking for vaccinations, meals, walks, weight, grooming and expenses	Combines consults with pet management in one Indian app	Few independent reviews found; no guided triage or species library evident

5.5 What the analysis shows

Finding	Implication for PetCare
Vet access in India is led by commerce players such as Supertails, where consults sit beside a store and pharmacy	PetCare's separation from medicine sales can be a trust advantage, which fits the client's decision to keep it separate
Clinic apps such as PetDesk show strong value in reminders and records, but depend on a clinic	Keep reminders and pet records in the MVP as a retention feature
TTcare shows demand for photo screening, but it makes diagnostic claims	Keep photos as optional context for the vet and defer AI to a later version, as already decided
TriageTail and Daisy show that urgency framing and follow-up questions are an emerging pattern	Keep the three urgency levels and add the follow-up screen in v2
Some Supertails reviews mention waiting and missing confirmation	Add clear booking status and a dedicated confirmation screen in v2 (already planned)
No single reviewed product combined guided triage, a dog and cat care library and a vet directory with booking for Indian owners	This is the opportunity PetCare can aim for. It needs checking against a wider scan of apps before you state it as a fact

6. Goals, features and MVP scope

6.1 Feature priorities

Feature	What the user can do	Priority
Home dashboard	Reach symptom check, pets, library, vets and care advice	Must
Pet profiles	Store species, breed, age, sex, weight	Must
Guided symptom checker	Choose symptoms, duration, severity, answer follow-ups, optionally add a photo	Must
Preliminary guidance	See urgency level, cautious next steps and emergency warning signs	Must
Animal library and details	Search dogs and cats; read diet, habitat, behaviour, exercise, common concerns, care needs	Must
Vet directory and profile	Search and compare vets by location, specialty and availability	Must
Appointment request	Pick a slot, add reason, submit and see confirmation	Must
Diet and care guides	Read general feeding and care guidance by species	Should
Basic reminders	Vaccination and check-up reminders	Should
Feedback on results	Rate whether guidance was helpful	Should
Photo-based AI analysis	Automated image assessment	Later
Video consultation	Live online consults	Later
Medicine catalogue link	Show approved client products	Later, if client confirms

6.2 Budget and MVP logic

The client mentioned an indicative budget of ₹2,00,000. Because only a wireframe is being delivered, the budget is used to decide what a realistic first working version could contain. The split below is a planning assumption for discussion, not a quotation. A developer estimate is needed before any commitment.

Work area	Illustrative allocation (₹)	Notes
Design refinement and clickable prototype	25,000	Finalise v2 screens and design system
Mobile app development (core screens)	90,000	Cross-platform build of the Must features
Backend and API development	45,000	Endpoints mapped in section 8.4, database, basic admin
Veterinary content and triage review	20,000	Qualified vet reviews guides and rules
Testing, deployment and store listing	10,000	QA, bug fixes, release
Contingency	10,000	Unforeseen work
Total	2,00,000	

Deferred to protect budget and safety: photo-based AI diagnosis, video consultations, a personalised diet engine, payments, and integration with the client's systems.

7. User journeys

7.1 Journey A: owner with a health concern

1. Home: tap “Check Symptoms”.
2. Choose the pet (or add a new one).
3. Select symptoms, duration and severity; optionally add a photo.
4. Answer a few follow-up questions.
5. Read the preliminary guidance and urgency level.
6. Choose “Find a Vet”, review a profile, pick a slot and request an appointment.
7. See the booking confirmation and what to bring.

7.2 Journey B: person deciding whether to get a pet

1. Home: open “Explore Animals”.
2. Search or filter dogs and cats.
3. Open an animal detail page.
4. Review diet, habitat, behaviour, exercise, common concerns and care needs.
5. Use “Ask a Vet About This Breed” to book a consult, or leave with a clearer view of fit.

7.3 Screen map

Journey	Screens in order
A: health concern	Home → Symptom Checker → Follow-up Questions* → Assessment Result → Vet Directory → Vet Profile → Appointment Booking → Booking Confirmation*
B: research a pet	Home → Animal Library → Animal Details → (optional) Vet Directory
Setup	Onboarding* → Home → My Pets → Add Pet*

* *Screens planned for version 2 of the wireframe.*

8. Wireframes

Nine screens were generated with Figma's AI tools using the prompts in Appendix A and reviewed by hand. Place names, clinic names, fees, dates and email addresses visible in the screens are sample data for illustration only. Some are UK-style placeholders and are scheduled to be localised for India in version 2 (section 11).

8.1 Screens 1–3: Home, My Pets, Symptom Checker

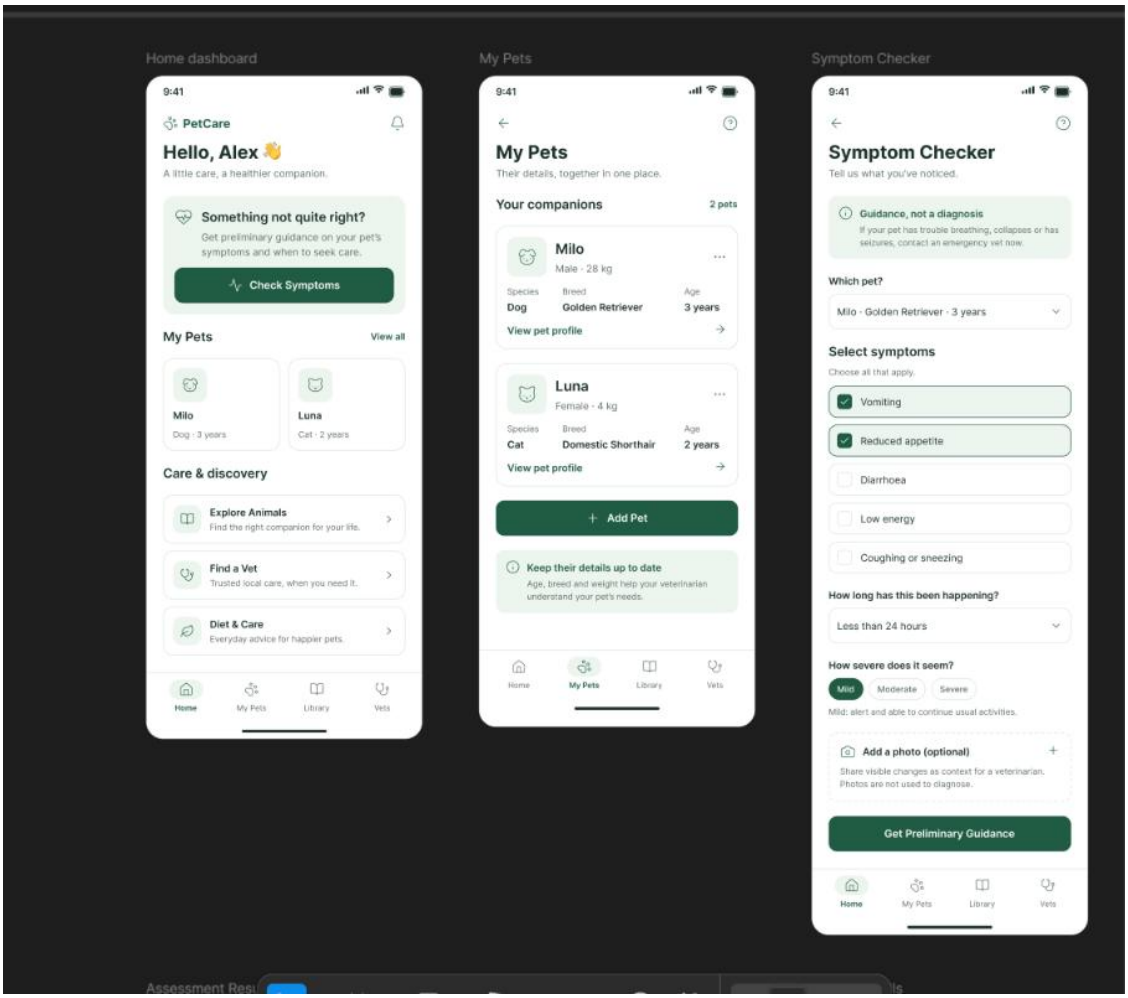

Figure 1. Home Dashboard, My Pets and Symptom Checker (Figma)

8.2 Screens 4–6: Assessment Result, Animal Library, Animal Details

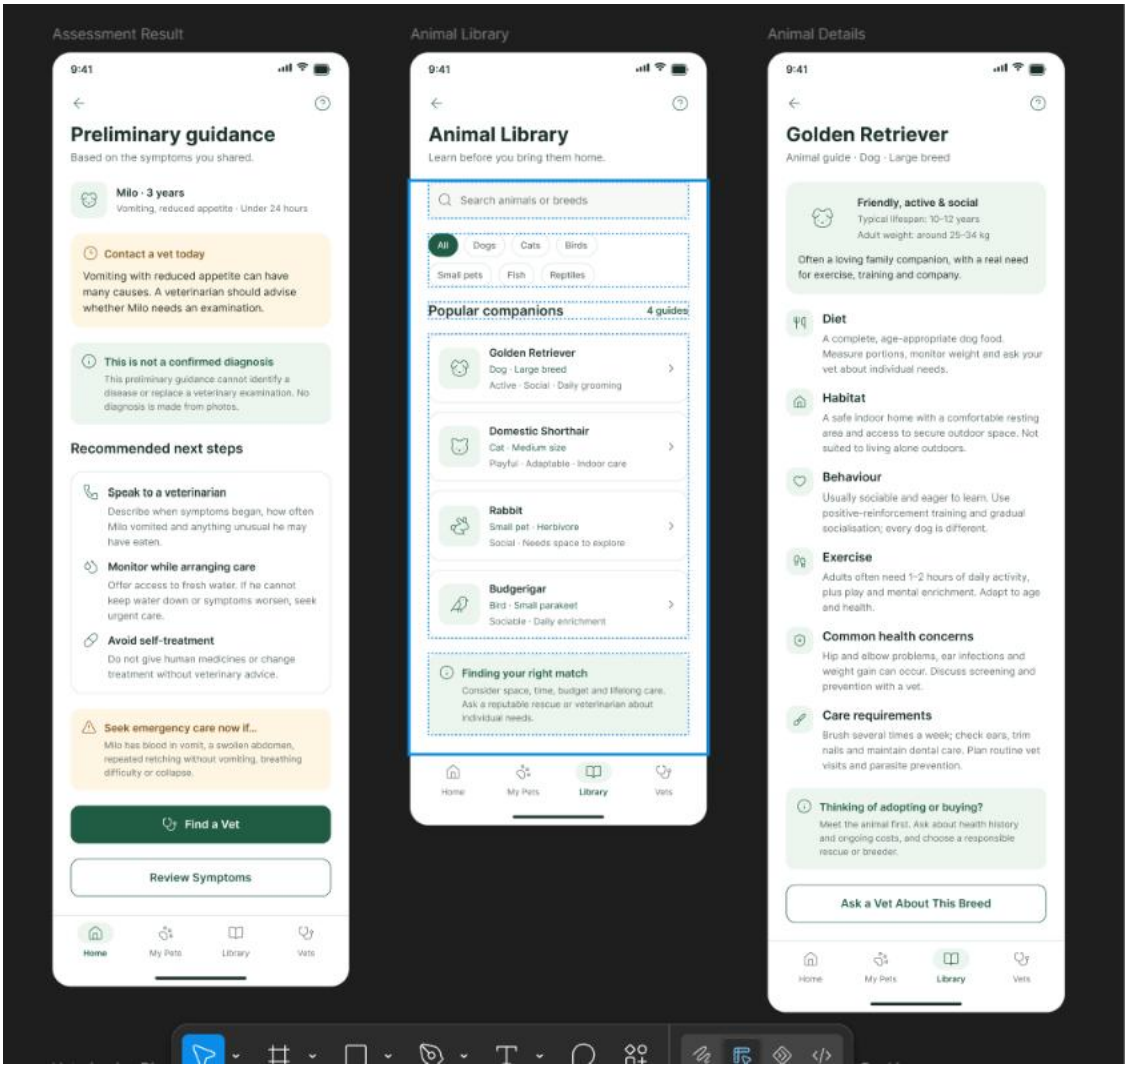

Figure 2. Assessment Result, Animal Library and Animal Details (Figma). The blue dashed outline on the library screen is a Figma selection guide, not part of the design.

8.3 Screens 7–9: Vet Directory, Vet Profile, Appointment Booking

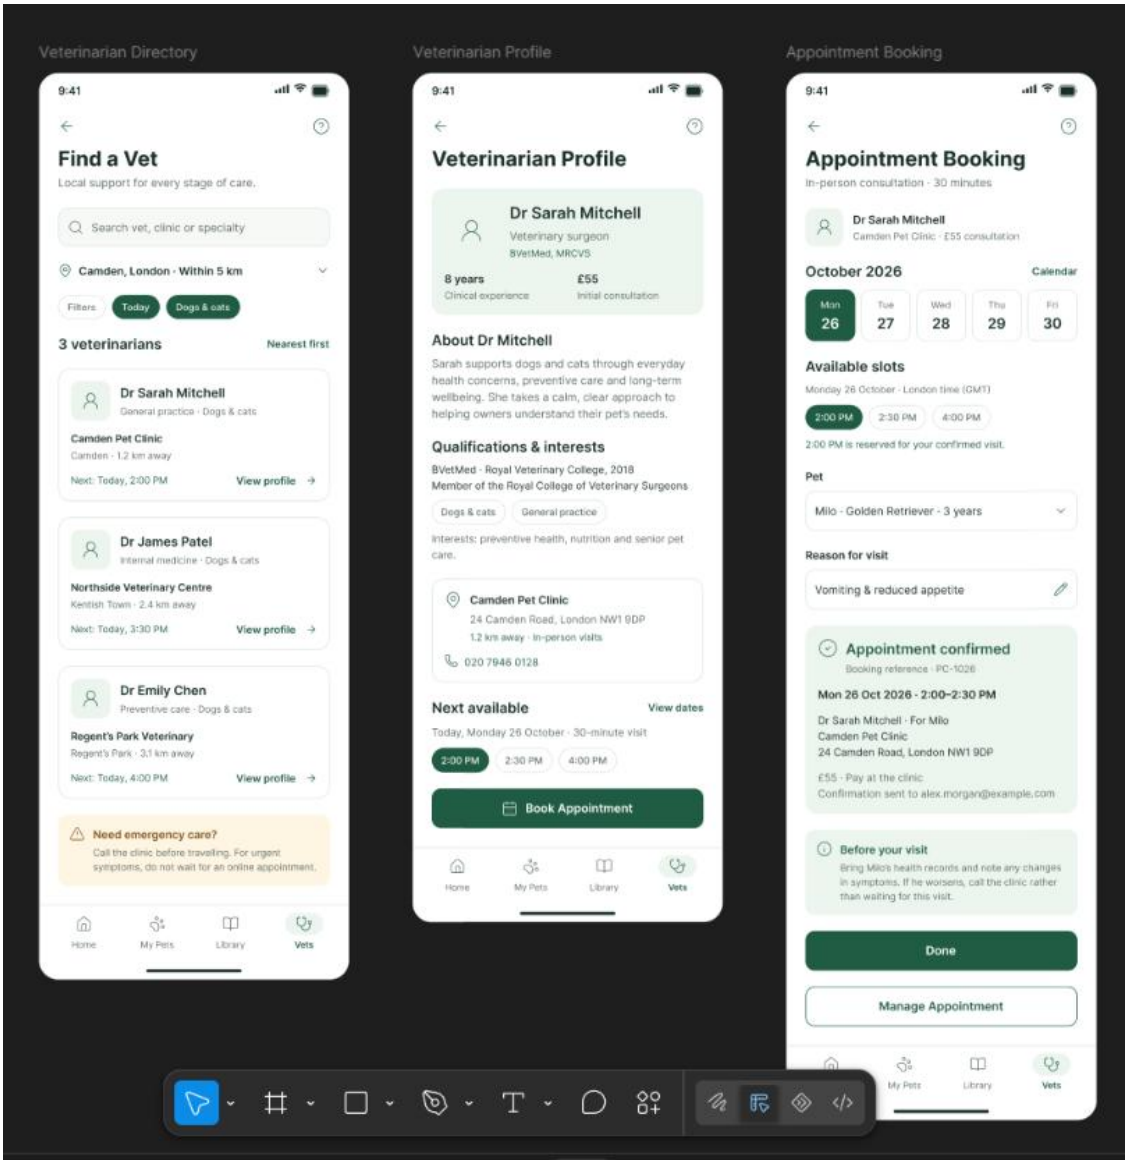

Figure 3. Veterinarian Directory, Veterinarian Profile and Appointment Booking (Figma)

8.4 Screen-by-screen guide

#	Screen	Purpose	Key elements	API used
1	Home Dashboard	Starting point for the main tasks	Health-check callout, pet cards, Explore Animals, Find a Vet, Diet and Care, bottom navigation	GET /pets
2	My Pets	View and manage animals	Pet cards (name, species, breed, age, weight), Add Pet	GET /pets, POST /pets
3	Symptom Checker	Collect structured symptom details	Pet selector, symptom checkboxes, duration, severity, optional photo, “guidance, not a diagnosis” notice	GET /symptoms, POST /assessments
4	Assessment Result	Explain a cautious next step	Pet summary, urgency notice, “not a confirmed diagnosis” box, next steps, emergency warning, Find a Vet	GET /assessments/{id}/recommendations
5	Animal Library	Browse animals before or after getting one	Search, category chips, animal cards, “finding your right match” note	GET /species
6	Animal Details	Explain care needs of one animal	Overview, diet, habitat, behaviour, exercise, common concerns, care, adoption note	GET /species/{id}, /care-guides, /diet-guides
7	Vet Directory	Find relevant vets	Search, location, filters, vet cards, emergency notice	GET /vets
8	Vet Profile	Help an informed choice	Credentials, experience, specialties, clinic, contact, next available slots	GET /vets/{id}, /availability
9	Appointment Booking	Request an appointment	Date and time slots, pet, reason for visit, confirmation summary	POST /appointments

Note: screen 9 currently combines the booking form and the confirmation state. Version 2 separates them.

9. Usability principles applied

The wireframes were checked against Nielsen's usability heuristics. "Planned" items are v2 changes, not yet in the screens.

Principle	How the design applies it	Status
Visibility of system status	Selected pet and symptoms are summarised on the result screen; a progress bar for the multi-step checker	Result: yes. Progress bar: planned
Match with the real world	Plain language such as "Not eating" and "Contact a vet today" rather than clinical terms	Yes
User control and freedom	Back arrows on every screen; "Review Symptoms" on the result; "Manage Appointment" after booking	Yes
Consistency and standards	Same palette, cards, buttons and bottom navigation across all screens	Yes
Error prevention	Symptom list with checkboxes instead of free text; emergency notice shown before the form	Yes
Recognition over recall	Chips, selectors and cards; pet and symptom shown again on later screens	Yes
Aesthetic and minimalist design	One main action per screen; light green cards to group content	Yes
Help users in emergencies	"Seek emergency care now if…" on the result; "Need emergency care?" on the vet directory	Yes
Accessibility	Readable type and clear contrast; minimum 44px tap targets	Check in v2

10. Symptom triage logic

> **Safety note**
> The rules below are an illustrative starting point for discussion, not veterinary advice. They must be reviewed and approved by a qualified veterinarian before use. The app gives preliminary guidance only and never a confirmed diagnosis.

10.1 Urgency levels

Level	Meaning	App response
Monitor	Mild and short-lived	Care tips, what to watch for, recheck in a set time
See a vet soon	Persistent, worsening or uncertain	Show vets and offer a booking within 1–2 days
Emergency	Possibly life-threatening	Tell the user to get urgent care now; show how to find or call the nearest clinic

10.2 Always-urgent signs (any species)

Difficulty breathing, seizures, collapse, pale gums, suspected poisoning, straining to urinate with little or no output, heavy bleeding, a swollen or hard abdomen, and repeated vomiting with inability to keep water down.

10.3 Example mapping (dogs and cats)

Owner says	Symptom	Follow-up questions	Raises urgency if	Next action
“Keeps throwing up”	Vomiting	How many times? Blood? Still drinking?	Repeated, blood, cannot keep water down, swollen belly	Monitor → vet soon → emergency
“Not eating”	Reduced appetite	How long? Low energy?	Over 24–48 hours, or with lethargy	Care tips or vet
“Loose motion”	Diarrhoea	How long? Blood?	Blood, black stool, very young or old pet, lasting 48+ hours	Monitor or vet
“Scratching a lot”	Itching	Where? Redness? Fleas seen?	Open sores, facial swelling	Care guide or vet
“Limping”	Lameness	Which leg? Sudden? Swelling?	Will not bear weight, visible deformity	Rest advice or vet
“Coughing or sneezing”	Respiratory signs	How long? Breathing effort?	Laboured breathing, blue or pale gums	Monitor, vet soon or emergency

Data model used by the checker: species → symptom → follow-up questions → red-flag rules → urgency level → general guidance → next action. Content sources must be reviewed; forum data is used only to learn how owners describe problems.

11. Analysis, iteration and usability test plan

11.1 Self-review of version 1

The following issues were identified by reviewing the nine screens against the brief. This is an expert self-review, not user testing.

#	Observation (v1)	Planned change (v2)	Source
1	Sample data is UK-style (London places, £ fees, UK credentials and phone) while the client budget is in ₹	Localise to Delhi NCR: ₹ fees, +91 numbers, Indian credentials, still labelled as sample data	Self-review
2	No onboarding screen and no add-pet screen	Add onboarding and an add-pet form	Self-review
3	No follow-up question screen, so every result looks similar	Add follow-up questions and vary urgency by answers	Self-review
4	Result shows one urgency banner but not the full scale	Add a three-level urgency strip (Monitor, See a vet soon, Emergency)	Self-review
5	Booking form and confirmation are on one screen	Split into booking and confirmation screens	Self-review
6	Symptom list is short (no limping or itching)	Add more common symptoms or a “More symptoms” option	Self-review
7	No way to rate a result	Add “Was this helpful?” row	Self-review
8	Reminders are in the feature list but not on a screen	Add a reminders card on Home	Self-review
9	Checker has no progress indicator	Add step progress (1 of 3)	Self-review

11.2 Usability test plan

Item	Plan
Goal	Check whether users can complete the main tasks and trust the guidance
Participants	4–5 pet owners or prospective owners, including at least one first-time owner
Prototype	Clickable Figma prototype of the main flows
Method	Moderated, think-aloud sessions of about 15 minutes. Script in Appendix C
Tasks	T1 add a pet. T2 check a symptom and find the urgency level. T3 find and request a vet appointment. T4 look up a dog breed and decide if it suits you. T5 find the emergency advice
Measures	Task success (yes, partly, no), time on task, errors, ease rating (1–7), comments
Ethics	Ask consent, explain it is a prototype, do not collect personal data, allow withdrawal

12. Risks, ethics and limitations

Risk	Why it matters	Mitigation
Users treat guidance as a diagnosis	A wrong assumption could delay care	Clear “not a diagnosis” wording, urgency levels, always show vet options and emergency signs
Unsafe or inaccurate content	Care and triage advice affects animal welfare	Vet review of all guides and rules before launch; show review date
Medicine misuse	Suggesting drugs without diagnosis is unsafe	No medicine recommendations or prescriptions in v1; catalogue integration only with veterinary controls
Photo over-reliance	A photo cannot reliably show a disease	Photo is optional context for the vet; no AI diagnosis claims
Fake or outdated vet data	Users could book with the wrong provider	Verify credentials and clinics; sample data clearly labelled in prototype
Privacy	Pet and owner data and location are sensitive	Collect minimum data, consent, secure storage, clear policy
Budget overrun	Advanced features can exceed ₹2,00,000	MVP scope, defer AI and video, get a developer estimate
Research bias	Small samples and forum data are not representative	State limits, triangulate with survey, interviews and expert review

Appendix A.

Prompt sheet -https://claude.ai/share/9d09b839-91ac-420f-ab7d-ca6528b02ac1
